**Subject: Preliminary Special-status Botanical Survey Report, Redwood Multipurpose Marine Terminal, Samoa, California**

Shane Phillips:

## Introduction

This preliminary special-status botanical survey report provides the results of protocol-level botanical surveys at the proposed Redwood Multipurpose Marine Terminal (RMMT) site in Samoa, California. The surveys were completed to inform conceptual planning for the proposed terminal and is intended as baseline information regarding the existing botanical resources within the study area.

This survey effort included botanical surveys following California Department of Fish & Wildlife (CDFW) protocol (CDFW, 2018) of the entire study area for presence of special-status plants and to determine suitability of habitat for the potential occurrence of special-status plant species.

## Site Description

The RMMT site is located on the Samoa Peninsula, a narrow peninsula that separates Humboldt Bay from the Pacific Ocean (Figure 1). The subject site has a long industrial history of timber production that has resulted in significant grading, infilling, and expansion over previous intertidal and dune lands along the Humboldt Bay shoreline. The majority of the study area has been previously developed with paved surfaces, foundations, drainageways and compacted soils remaining following demolitions of structures and industrial facilities. Consequently, the majority of the site is dominated by non-native, ruderal species or is unvegetated where concrete and asphalt remains. Natural vegetation does still occur within the study area, but it is sparse and patchy, separated by large, formerly developed areas. Intact native vegetation occurs along the periphery of the study area especially along Humboldt Bay in the northern portion of the study area and along Vance Avenue in the southwestern portion of the study area. Many of the native vegetation areas meet the criteria for sensitive vegetation communities and will be considered Environmentally Sensitive Habitat Areas (ESHA) by the California Coastal Commission.

## **Survey Methods**

A review of existing data and information related to special-status plant species that may have the potential to occur within the study area was compiled from several sources (CDFW, 2022a, 2022b; CNPS, 2022; USFWS, 2022) (see Attachment 1, Table 1). Plants observed during site visits were identified to the lowest taxonomic level possible to distinguish special-status species from others. Based on the list of special-status species with potential to occur onsite, suitable habitat availability for each species was determined using the following criteria:

- **None.** Species listed as having “none” are those species for which:
  - there is no suitable habitat present in the study area (that is, habitats in the study area are unsuitable for the species requirements [for example, elevation, hydrology, plant community, disturbance regime, etc.]).
- **Low.** Species listed as having a “low” potential to occur in the study area are those species for which:
  - there is no known record of occurrence in the vicinity, and
  - there is marginal or very limited suitable habitat present within the study area.
- **Moderate.** Species listed as having a “moderate” potential to occur in the study area are those species for which:
  - there are known records of occurrence in the vicinity, and
  - there is suitable habitat present in the study area.
- **High.** Species listed as having a “high” potential to occur on the study area are those species for which:
  - there are known records of occurrence in the vicinity (there are many records and/or records in close proximity), and
  - there is highly suitable habitat present in the study area.
- **Present.** Species listed as “present” in the study area are those species for which:
  - the species was observed in the study area.

## **Results**

A total of 346 botanical species were observed within the study area (see Figures 1 and 2). Species composition was 51% native, reflecting the history of use onsite. Varied habitat from salt marsh to remnant dune habitat in addition to the introduction of non-native species has resulted in a high level of plant diversity within the study area. Suitable habitat is available onsite for 17 out of the 49 special-status plant species on the scoping list. Three special-status plant species were observed within the study area during surveys (*Angelica lucida*, *Castilleja ambigua* var. *humboldtiensis*, and *Chloropyron maritimum* ssp. *Palustre*); see Figures 2, 3, and 4), and two additional species (*Gilia millefoliata*) and (*Erysimum menziesii*) were observed immediately west of the study area. See Appendix 1, Table 1 for special-status plant species known to occur in the vicinity and their potential to occur within the study area, and Appendix 1, Table 2 for all plant species observed during protocol surveys.
